Laplace Exercise

John Urbanic
Parallel Computing Scientist
*Pittsburgh Supercomputing Center*

Our Exercise: Laplace Solver

Once Again, but this will be a little different where the OpenMP and OpenACC were similar.

OpenACC was the same idea as OpenMP, but with data migration added.

We never had to go beyond the mail loops.

This will require us to consider the entire code.

Initial Conditions

Metal Plate

Heating Element

Final Steady State

Metal Plate
Serial C Code (kernel)

```c
while ( dt > MAX_TEMP_ERROR && iteration <= max_iterations ) {

    for(i = 1; i <= ROWS; i++) {
        for(j = 1; j <= COLUMNS; j++) {
            Temperature[i][j] = 0.25 * (Temperature_last[i+1][j] + Temperature_last[i-1][j] +
                                        Temperature_last[i][j+1] + Temperature_last[i][j-1]);
        }
    }

    dt = 0.0;

    for(i = 1; i <= ROWS; i++){
        for(j = 1; j <= COLUMNS; j++){
            dt = fmax( fabs(Temperature[i][j]-Temperature_last[i][j]), dt);
            Temperature_last[i][j] = Temperature[i][j];
        }
    }

    if((iteration % 100) == 0) {
        track_progress(iteration);
    }

    iteration++;

}
```

Done?

Calculate

Update temp array and find max change

Serial C Code Subroutines

```c
void initialize(){

    int i,j;

    for(i = 0; i <= ROWS+1; i++){
        for (j = 0; j <= COLUMNS+1; j++){
            Temperature_last[i][j] = 0.0;
        }
    }

    // these boundary conditions never change throughout run

    // set left side to 0 and right to a linear increase
    for(i = 0; i <= ROWS+1; i++) {
        Temperature_last[i][0] = 0.0;
        Temperature_last[i][COLUMNS+1] = (100.0/ROWS)*i;
    }

    // set top to 0 and bottom to linear increase
    for(j = 0; j <= COLUMNS+1; j++) {
        Temperature_last[0][j] = 0.0;
        Temperature_last[ROWS+1][j] = (100.0/COLUMNS)*j;
    }
}
```

```c
void track_progress(int iteration) {

    int i;

    printf("-- Iteration: %d --\n", iteration);
    for(i = ROWS-5; i <= ROWS; i++) {
        printf("[%d,%d]: %5.2f ", i, i,Temperature[i][i]);
    }
    printf("\n");
}
```

BCs could run from 0 to ROWS+1 or from 1 to ROWS. We chose the former.

```
First Things First: Domain Decomposition

- All processors have entire T array.
- Each processor works on TW part of T.
- After every iteration, all processors broadcast their TW to all other processors.
- Increased memory. NOT SCALABLE!
- Global (message passing) variables are ALWAYS bad!

Try Again: Domain Decomposition II

- Each processor has sub-grid.
- Communicate boundary values only.
- Reduces memory.
- Reduces communications.
- Have to keep track of neighbors in two directions.
- But not too bad.
Simplest:
Domain Decomposition III

- Only have to keep track of up/down neighbors, and no corner case.

- Scales, as below. How would we handle 5 PEs with the "square decomposition"?

Simplest Decomposition for C Code

Simplest Decomposition for C Code

In the parallel case, we will break this up into 4 processors. There is only one set of boundary values. But when we distribute the data, each processor needs to have an extra row for data distribution, these are commonly called the "ghost cells".
The program has a local view of data. The programmer has to have a global view of data. The ghost cells don't exist in the global dataset. They are only copies from the "real" data in the adjacent PE.

Sending Multiple Elements

- For the first time we want to send multiple elements. In this case, a whole row or column of data. That is exactly what the count parameter is for.

- The common use of the count parameter is to point the Send or Receive routine at the first element of an array, and then the count will proceed to strip off as many elements as you specify.

- This implies (and demands) that the elements are contiguous in memory. That will be true for one dimension of an array, but the other dimension(s) will have a stride.

- In C this is true for our rows. In Fortran this is true for our columns. This will give us a strong preference for the problem orientation in each language. Then we don't have to worry about strides in the strips that we send.

- However, it is very often necessary to send messages that are not contiguous data. Using defined data types, we can send other array dimensions, or even blocks or surfaces. We will talk about that capability in the Advanced talk.

PITTSBURGH
SUPERCOMPUTING
CENTER

Sending Multiple Elements
C:

This last index is the one contiguous in memory.

int A[8][12];

MPI_Send(&A[3][1], 4, MPI_INT, pe, tag, MPI_COMM_WORLD);

Fortran:

integer A(0:7,0:11)

MPI_Send(A(3,1), 4, MPI_INT, pe, tag, MPI_COMM_WORLD, err);

This first index is the one contiguous in memory.

Array Ordering

Once again, we will make this issue less critical from the MPI perspective once we learn about user defined datatypes in the advanced talk, but…

this is extremely important to understand for general performance reasons. Notice how the C code iterates over the last (j) variable in the inner loop while the Fortran uses the first (i) in our serial code? This would kill our performance if it was the other way around. And I mean in the serial code. Go ahead and try…

```
for(i = 1; i <= ROWS; i++) {
    for(j = 1; j <= COLUMNS; j++) {
        Temperature[i][j] = 0.25 * (Temperature_last[i+1][j] + Temperature_last[i-1][j] +
                                    Temperature_last[i][j+1] + Temperature_last[i][j-1]);
    }
}
```
```
do j=1,columns
    do i=1,rows
        temperature(i,j)= 0.25 * (temperature_last(i+1,j)+temperature_last(i-1,j) + &
                                  temperature_last(i,j+1)+temperature_last(i,j-1) )
    enddo
enddo
```
Sending Multiple Elements

```
if ( mype != 0 ){
    up = mype - 1
    MPI_Send( t, COLUMNS, MPI_FLOAT, up, UP_TAG, comm);
}

Alternatively
up = mype - 1
if ( mype == 0 ) up = MPI_PROC_NULL;
MPI_Send( t, COLUMNS, MPI_FLOAT, up, UP_TAG, comm);
```
Simplest Decomposition for Fortran Code

Simplest Decomposition for Fortran Code

Then we send strips to ghost zones like this:

Same ghost cell structure as the C code, we have just swapped rows and columns.
Sending Multiple Elements in Fortran

```fortran
if( mype.ne.0 ) then
    left = mype - 1
    call MPI_Send( t, ROWS, MPI_REAL, left, L_TAG, comm, ierr)
endif
```

Alternatively

```fortran
left = mype - 1
if( mype.eq.0 ) left = MPI_PROC_NULL
call MPI_Send( t, ROWS, MPI_REAL, left, L_TAG, comm, ierr)
endif
```

Note: You may also `MPI_Recv` from `MPI_PROC_NULL`

Main Loop Structure

```
for (iter=1; iter < NITER; iter++) {
    Do averaging
    Copy Temperature into Temperature_last
```

Compute Phase
(almost unchanged)

| |
|---|
| Send real values down
Temperature or Temperature_last ? |
| Send real values up |
| Receive values from above into ghost zone |
| Receive values from below into ghost zone
Temperature or Temperature_last? |
| Find the max change |
| Synchronize? |

Communicate Phase
(all new)

Boundary Conditions

Both C and Fortran will need to set proper boundary conditions based upon the PE number.

Two ways to approach this exercise.

- Start from the serial code
- Start from the template ("hint") code

Starting files in Exercises/MPI:

```
laplace_serial.c            laplace_serial.f90
laplace_template.c          laplace_template.f90
```

You can peek at my answer in /Solutions

```
laplace_mpi.c               laplace_mpi.f90
```

MPI Template for C

```c
.
.
int main(int argc, char *argv[]) {

    int i, j;
    int max_iterations;
    int iteration=1;

    // the usual MPI startup routines
>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

    // verify only NPES PEs are being used
>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

    // PE 0 asks for input
>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

    // bcast max iterations to other PEs
>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

    if (my_PE_num==0) gettimeofday(&start_time,NULL);

    initialize(npes, my_PE_num);

    while ( dt_global > MAX_TEMP_ERROR && iteration <= max_iterations ) {

        // main calculation: average my four neighbors
        for(i = 1; i <= ROWS; i++) {
            for(j = 1; j <= COLUMNS; j++) {
                Temperature[i][j] = 0.25 * (Temperature_last[i+1][j] + Temperature_last[i-1][j] +
                                            Temperature_last[i][j+1] + Temperature_last[i][j-1]);
            }
        }

        // COMMUNICATION PHASE: send and receive ghost rows for next iteration
>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

        dt = 0.0;
.
.
```

MPI Template for Fortran

```fortran
.
.
program mpi
    implicit none
    include    'mpif.h'

    !Size of plate
    integer, parameter          :: columns_global=1000
    integer, parameter          :: rows=1000

    double precision, dimension(0:rows+1,0:columns+1) :: temperature, temperature_last

    !usual mpi startup routines
>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

    !It is nice to verify that proper number of PEs are running
>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

    !Only one PE should prompt user
    if( mype == 0 ) then
        print*, 'Maximum iterations [100-4000]?'
        read*,   max_iterations
    endif

    !Other PEs need to recieve this information
>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

    call cpu_time(start_time)

    call initialize(temperature_last, npes, mype)

    !do until global error is minimal or until maximum steps
    do while ( dt_global > max_temp_error .and. iteration <= max_iterations)

        do j=1,columns
            do i=1,rows
                temperature(i,j)=0.25*(temperature_last(i+1,j)+temperature_last(i-1,j)+ &
                                       temperature_last(i,j+1)+temperature_last(i,j-1) )
            enddo
        enddo
```

Some ways you might go wrong...

You have two main data structures

- Temperature
- Temperature_last

Each has

- Boundary Conditions (unchanged through entire run)
- Ghost zones (changing every timestep)

Each iteration

- Copying/calculating Temperature to/from Temperature_last
- Sending/receiving into/from ghost zones and data

It is easy to mix these things up. I suggest you step through at least the initialization and first time step for each of the above combinations of elements.

There are multiple reasonable solutions. Each will deal with the above slightly differently.

How do you know you are correct?

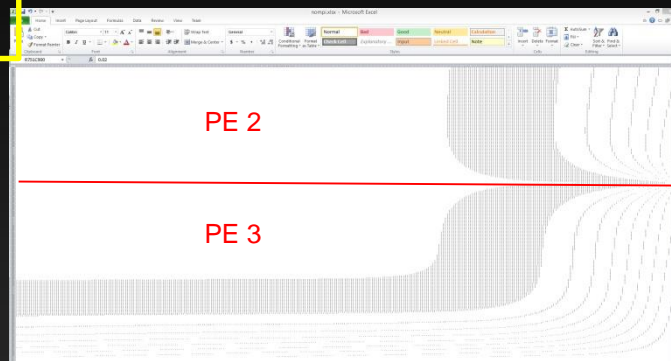

Your solution converges
at 3372 timesteps!

PE 2

PE 3

MPI Routines Disabled

Both converge at 3372 steps!

All the action is here.

Check for yourself.

```c
void output(int my_pe, int iteration) {

  FILE* fp;
  char filename[50];

  sprintf(filename,"output%d.txt",iteration);

  for (int pe = 0; pe<4; pe++){
    if (my_pe==pe){

      fp = fopen(filename, "a");

      for(int y = 1; y <= ROWS; y++){
        for(int x = 1; x <= COLUMNS; x ++){
          fprintf(fp, "%5.2f ",Temperature[y][x]);
        }
        fprintf(fp,"\n");
      }

      fflush(fp);
      fclose(fp);

    }
    MPI_Barrier(MPI_COMM_WORLD);

  }

}
```

```
C:
if (my_PE_num==2)
      printf("Global coord [750,900] is %f \n:", Temperature[250][900]);

Fortran:
if (mype==2) then
      print*, 'magic point', temperature(900,250)
endif
```

Magic
Point → O
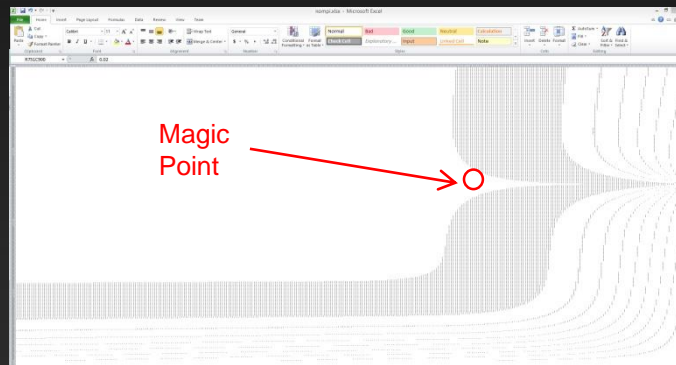

- Human Readable
- 1M entries
- Visualize. I used Excel (terrible idea).

- If about 1.0, probably good
- Otherwise (like 0.02 here) probably not

A Quick Note About Our Pace Before We Start

This exercise is doable during the exercise session time allotted if all goes well.

That has been our historical standard.

However some of you may need a little more time. That is fine.

We will not "spoil" the exercise during the Laplace Exercise Review tomorrow.

Those of you that need additional time can use your accounts through next week.

Please take advantage of that. **If you complete this exercise, you understand MPI.**

Laplace Exercise

1. You copied a directory called Exercises/MPI into your home directory. Go there and you will see the files:

```
laplace_template.c and laplace_serial.c
                    or
laplace_template.f90 and laplace_serial.f90
```

2. The templates are "hint" files with sections marked >>>>> in the source code where you might add statements so that the code will run on 4 PEs. You can start from either these or from the serial code, whichever you prefer. A useful Web reference for this exercise is the Message Passing Interface Standard at:

<center>http://www.mpich.org/static/docs/latest/www/</center>

3. To compile the program as it becomes an MPI code, execute:
```
mpicc laplace_your_mpi.c
mpif90 laplace_your_mpi.f90
```

4. In an interactive session (with at least 4 Pes: "interact –n 4"), you can just run these as:
```
mpirun –n 4 a.out
```

5. You can check your program against one possible solution in the Solutions directory:
```
laplace_mpi.c  or  laplace_mpi.f90
```

6. When you are done, let us know by hitting the survey button on the workshop page: bit.ly/XSEDE-Workshop
